

Introducing the Java (Cont.2)

Rules for Creating Statements

- Use a semicolon to terminate statements.
- Define multiple statements within braces.
- Use braces for control statements.

Control Statements

Categorizing Basic Flow Control Types

Flow control can be categorized into four types:

Sequential

Iteration

Selection

Transfer

Control Statements

Using Flow Control in Java

- Each simple statement terminates with a semicolon (;).
- Group statements by using the braces { }.
- Each block executes as a single statement within the flow of control structure.

```
{  
    boolean finished = true;  
    System.out.println("i = " + i);  
    i++;  
}
```

Creating Code Blocks

- Enclose all class declarations.
- Enclose all method declarations.
- Group other related code segments.

```
public class SayHello {  
    public static void main(String[] args) {  
        System.out.println("Hello world");  
    }  
}
```

The diagram illustrates the nesting of code blocks. A large outer rectangle encloses the entire code snippet. Inside it, a smaller rectangle encloses the class body (from the opening curly brace to the closing curly brace). Inside that, another rectangle encloses the method body (from the opening curly brace of the main method to its closing curly brace). Arrows point from the text labels in the list above to these specific parts of the code: 'Enclose all class declarations' points to the outermost curly braces, 'Enclose all method declarations' points to the innermost curly braces, and 'Group other related code segments' points to the space between the class and method braces.

You never need to destroy an object

Scoping: { }

```
{  
    int x = 12;  
    /* only x available */  
    {  
        int q = 96;  
        /* both x & q available */  
    }  
    /* only x available */  
    /* q “out of scope” */  
}
```

determines the visibility
and lifetime of the names
defined within that scope.

```
{  
    int x = 12;  
    { ??????????????????????  
        int x = 96; /* illegal */  
    }  
}
```

You never need to destroy an object

Scoping: { }

Scope of objects

vanishes at the end of the scope,

but the String object that s was pointing to is still occupying memory.

garbage collector

```
{  
    String s = new String("a string");  
} /* end of scope */
```

Control Statements

- **Three types of selection statements.**

1. if Single-Selection Statement

```
if ( studentGrade >= 60 )  
    System.out.println( "Passed" );
```

2. if...else Double-Selection Statement

```
if ( grade >= 60 )  
    System.out.println( "Passed" );  
else  
    System.out.println( "Failed" );
```

Can test multiple cases by placing if...else statements inside other if...else statements to create **nested if...else**

```
if ( studentGrade >= 90 )  
    System.out.println( "A" );  
else if ( studentGrade >= 80 )  
    System.out.println( "B" );  
else if ( studentGrade >= 70 )  
    System.out.println( "C" );  
else if ( studentGrade >= 60 )  
    System.out.println( "D" );  
else  
    System.out.println( "F" );
```

Control Statements

- **Three types of selection statements. (Cont.1)**

2. if...else Double-Selection Statement (Cont.1)

Conditional operator (?:)—shorthand if...else.

Ternary operator (takes three operands)

Operands and ?: form a **conditional expression**

Example:

```
System.out.println(  
    studentGrade >= 60 ? "Passed" : "Failed" );
```

Control Statements

- **Three types of selection statements. (Cont.1)**

2. if...else Double-Selection Statement (Cont.2)

```
if ( x > 5 )  
{  
    if ( y > 5 )  
        System.out.println( "x and y are > 5" );  
}
```

```
else  
    System.out.println( "x is <= 5" );
```

```
if ( grade >= 60 )  
    System.out.println("Passed");  
else  
{  
    System.out.println("Failed");  
    System.out.println("You must take this course again.");  
}
```

Control Statements

- **Three types of selection statements. (Cont.1)**

3. switch statement

- Case labels must be constants.
- Use break to jump out of a switch.
- It is recommended to always provide a default.

```
switch (choice) {  
    case 37:  
        System.out.println("Coffee?");  
        break;  
  
    case 45:  
        System.out.println("Tea?");  
        break;  
  
    default:  
        System.out.println("???");  
}
```

There are situations where falling through can be useful.
To fall through, simply **do not include a break.**

Control Statements

- **Three repetition statements (also called looping statements)**
Repetition statement's body may be a **single** statement or a **block** { }
- **while** statement
- **for** statement
- **The do...while**

Looping in Java

- There are three types of loops in Java:
 - while
 - do...while
 - for
- All loops have four parts:
 - Iteration condition
 - Body
 - Initialization
 - Termination

Using the while Loop

`while` is the simplest loop statement and contains the following general form:

```
while ( boolean_expr )  
    statement;
```

Example:

```
int i = 0;  
while (i < 10) {  
    System.out.println("i = " + i);  
    i++;  
}
```

Using the do...while Loop

do...while loops place the test at the end:

```
do
    statement;
while ( termination );
```

Example:

```
int i = 0;
do {
    System.out.println("i = " + i);
    i++;
} while (i < 10);
```

Using the for Loop

for loops are the most common loops:

```
for ( initialization; termination; iteration )  
    statement;
```

Example:

```
for (i = 0; i < 10; i++)  
    System.out.println(i);
```

How would this for loop look using a while loop?

More About the for Loop

- Variables can be declared in the initialization part of a for loop:

```
for (int i = 0; i < 10; i++)  
    System.out.println("i = " + i);
```

- Initialization and iteration can consist of a list of comma-separated expressions:

```
for (int i = 0, j = 10; i < j; i++, j--) {  
    System.out.println("i = " + i);  
    System.out.println("j = " + j);  
}
```

Guided Practice: Spot the Mistakes

```
int x = 10;  
while (x > 0);  
    System.out.println(x--);  
System.out.println("We have lift off!");
```

Extra semicolon
while (x > 0)
; // null loop body

```
int x = 10;  
while (x > 0)  
    System.out.println("x is " + x);  
x--;
```

2

**Outside the
loop**

```
int sum = 0;  
for (; i < 10; sum += i++);  
System.out.println("Sum is " + sum);
```

i is not initialized anywhere

Form of the infinite loop is:

for(;;)

while(true)

break and continue

You can also **control the flow of the loop** inside the body of any of the iteration statements by using **break** and **continue**.

Break quits the loop without executing the rest of the statements in the loop.

Continue stops the execution of the current iteration and goes back to the beginning of the loop to begin the next iteration.

```

package exh;
import java.util.*;

public class BM {
    public static void main(String[] args) {

        int a = 1 ;

        for(int i = 0; i < 128; i++){

            if ( i == 120 )
                break;

            if ( i == 100 || i == 101 )
                continue;

            if (Character.isLowerCase((char)i))

                System.out.println("value: " + i + " character: " + (char)i);
        }
        System.out.println("-----");

    } }

```

```

value: 97 character: a
value: 98 character: b
value: 99 character: c
value: 102 character: f
value: 103 character: g
value: 104 character: h
value: 105 character: i
value: 106 character: j
value: 107 character: k
value: 108 character: l
value: 109 character: m
value: 110 character: n
value: 111 character: o
value: 112 character: p
value: 113 character: q
value: 114 character: r
value: 115 character: s
value: 116 character: t
value: 117 character: u
value: 118 character: v
value: 119 character: w
-----

```

break and continue **label**

label1:

outer-iteration {

inner-iteration {

//...

break; // 1

//...

continue; // 2

//...

continue label1; // 3

//...

break label1; // 4

}

}

the break breaks out of the inner iteration and you end up in the outer iteration.

break and continue **label**

```
label1:
  outer-iteration {
    inner-iteration {
      //...
      break;           // 1
      //...
      continue;        // 2
      //...
      continue label1;  // 3
      //...
      break label1;     // 4
    }
  }
```

the continue moves back to the beginning of the inner iteration.

break and continue **label**

label1:

outer-iteration {

inner-iteration {

//...

break; // 1

//...

continue; // 2

//...

continue label1; // 3

//...

break label1; // 4

}

}

the continue label1 breaks out of the inner iteration *and* the outer iteration, all the way back to label1. Then it does in fact continue the iteration, but starting at the outer iteration.

break and continue **label**

```
label1:
  outer-iteration {
    inner-iteration {
      //...
      break;           // 1
      //...
      continue;        // 2
      //...
      continue label1; // 3
      //...
      break label1;    // 4
    }
  }
```

the break label1 also breaks all the way out to label1, but it does not reenter the iteration. It actually does break out of both iterations.

```

public class BM {
    public static void main(String[] args) {
        int i = 0;

        outer: // Can't have statements here

        for(; true ;) { // infinite loop

            inner: // Can't have statements here

            for(; i < 10; i++) {
                System.out.println("i = " + i);

                if(i == 2) {System.out.println("continue"); continue;}

                if(i == 3) {System.out.println("break");
                    i++; // Otherwise i never gets incremented.
                    break; }

                if(i == 7) {System.out.println("continue outer");
                    i++; // Otherwise i never gets incremented.
                    continue outer; }

                if(i == 8) {System.out.println("break outer"); break outer;}

                for(int k = 0; k < 5; k++) {

                    if(k == 3) {System.out.println("continue inner");
                        continue inner;} }

                }
            }
        }
    }
}

```

```

i = 0
continue inner
i = 1
continue inner
i = 2
continue
i = 3
break
i = 4
continue inner
i = 5
continue inner
i = 6
continue inner
i = 7
continue outer
i = 8
break outer

```

Implementing the break Statement

- Breaks out of a loop or switch statement
- Transfers control to the first statement after the loop body or switch statement
- Can simplify code but should be used sparingly

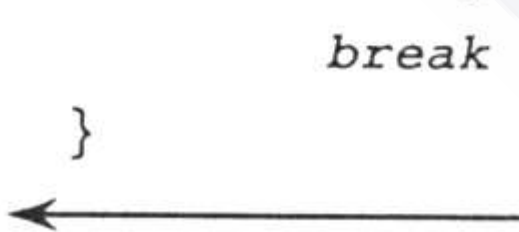

```
...  
while (age <= 65) {  
    balance = (balance+payment) * (1 + interest);  
    if (balance >= 250000)  
        break;  
    age++;  
}  
... ←
```

Comparing Labeled break and continue Statements

Can be used to break out of nested loops or continue a loop outside the current loop:

```
outer_loop:
for (int i = 0; i < 10; i++) {
    for (int j = 0; j < 5; j++) {
        System.out.println(i);
        System.out.println(j);
        if (i + j > 7)
            break outer_loop;
    }
}
...

```

A diagram illustrating the effect of the 'break outer_loop;' statement. A vertical line descends from the 'break outer_loop;' line, then turns left as an arrow pointing to the closing curly brace of the 'outer_loop' block, indicating that the loop is terminated immediately.

Compound Assignment Operators

Assignment operator	Sample expression	Explanation	Assigns
<i>Assume: int c = 3, d = 5, e = 4, f = 6, g = 12;</i>			
<code>+=</code>	<code>c += 7</code>	<code>c = c + 7</code>	10 to c
<code>-=</code>	<code>d -= 4</code>	<code>d = d - 4</code>	1 to d
<code>*=</code>	<code>e *= 5</code>	<code>e = e * 5</code>	20 to e
<code>/=</code>	<code>f /= 3</code>	<code>f = f / 3</code>	2 to f
<code>%=</code>	<code>g %= 9</code>	<code>g = g % 9</code>	3 to g

Fig. 4.13 | Arithmetic compound assignment operators.

Increment and Decrement Operators

Operator	Operator name	Sample expression	Explanation
++	prefix increment	++a	Increment a by 1, then use the new value of a in the expression in which a resides.
++	postfix increment	a++	Use the current value of a in the expression in which a resides, then increment a by 1.
--	prefix decrement	--b	Decrement b by 1, then use the new value of b in the expression in which b resides.
--	postfix decrement	b--	Use the current value of b in the expression in which b resides, then decrement b by 1.

Fig. 4.14 | Increment and decrement operators.

Logical Operators

- ▶ Java's **logical operators** enable you to form more complex conditions by combining simple conditions.
- ▶ The logical operators are
 - **&&** (conditional AND)
 - **||** (conditional OR)
 - **&** (boolean logical AND)
 - **|** (boolean logical inclusive OR)
 - **^** (boolean logical exclusive OR)
 - **!** (logical NOT).
- ▶ [*Note:* The **&**, **|** and **^** operators are also bitwise operators when they are applied to integral operands.]

Operators	Associativity	Type
++ --	right to left	unary postfix
++ -- + - ! (type)	right to left	unary prefix
* / %	left to right	multiplicative
+ -	left to right	additive
< <= > >=	left to right	relational
== !=	left to right	equality
&	left to right	boolean logical AND
^	left to right	boolean logical exclusive OR
	left to right	boolean logical inclusive OR
&&	left to right	conditional AND
	left to right	conditional OR
?:	right to left	conditional
= += -= *= /= %=	right to left	assignment

Fig. 5.19 | Precedence/associativity of the operators discussed so far.
